

S3 from AWS :

This service from AWS allows has to even launch a static website, apart from storing objects. Objects are stored in Buckets.

We have to create a bucket and we have to edit the static web hosting enable it and bucket policy is generated

The index file has to be given in the required field in the static web hosting section, so that the output of that file will be shown as a front-end user interface in the browser when the app is launched

In the buckets we can go to properties and in that we can get the website
