

RDS and EC2:

AWS provides us with an option to make a connection between RDS and EC2. Once a database of our choice has been created using the service RDS, we can make it connect with the EC2 from the "ACTIONS" section. The requisite to establish a connection is that both the database and the instance must be present in the same VPC region.

mysql -h <endpoint> -u <username> -p <password to be entered when asked>

it is used to connect the database from the ec2 it gives the secure connect when we enter the password to that in the starting of the creating database

after this we can perform all the operations in the database like creating and insterting etc

create database <database name>;

use <database name>;

insert into <table name> values(values);
